Solution

#### Motivation

- Cyber-physical system typically employ wireless sensors for keeping track of physical processes such as temperature and pressure. These nodes then transmit data packets containing measurements back to the access point.
- ▶ The Time between successive deliveries of packets is an important metric.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

 Wireless sensors are battery powered. Thus, energy-efficiency is also important.

## System Model

◆□ → ◆昼 → ◆臣 → ◆臣 → ◆ ● ◆ ◆ ● ◆

- Assumption: The Time is discrete.
- At most *L* sensors can simultaneously transmit in a time slot.

Channel : unreliable

For client n :

- Packet success probability:  $P_n \in (0,1)$
- Each attempt consumes E<sub>n</sub> units of energy

#### **Problem statement**

- **Ojectives:** regularity and energy-efficiency
- Designing a wireless scheduling policies that support the inter-delivery requirements of such wireless clients in an energy-efficient way.
- The QoS requirement of client n is specified through an integer , the packet inter-delivery time threshold  $\tau_n$ .

Access point Goal: To select at most L clients to transmit in each time-slot from among the N clients, so as to minimize the cost function.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

#### Cost function

The cost function incurred by the system during the time interval  $\{0,1,2,\ldots,T\}$  is given by,

$$E\left[\sum_{n=1}^{N} \left(\sum_{i=1}^{M_{T}^{(n)}} (D_{i}^{(n)} - \tau_{n})^{+} + \left(T - t_{D_{M_{T}^{(n)}}^{(n)}} - \tau_{n}\right)^{+} + \eta \hat{M}_{T}^{(n)} E_{n}\right)\right]$$
(1)

 $\begin{array}{ll} D_i^{(n)} & : \text{ time between the deliveries of the } i\text{-th and (i+1)-th packets for client } n.\\ M_T^{(n)} & : \text{ The number of packets delivered for the } n\text{-th client by the time } T.\\ t_{D_i^{(n)}} & : \text{ Time slot in which the } i\text{-th packet for client } n \text{ is delivered.}\\ \hat{M}_T^{(n)} & : \text{ Total number of slots in } \{0,1,\ldots,\text{T-1}\} \text{ in which the n-th client is selected to transmit.} \end{array}$ 

 $\eta$  : energy efficiency parameter.

()

#### Solution steps

- step 1: The problem formulated as MDP (Infinite state MDP)
- step 2: Reduce it to an equivalent finite state MDP
- step 3: To decrease the computational complexity, finite state MDP formulated as a restless multi-armed bandit problem, with the goal of exploiting a low-complexity index policy

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへで

#### Reduction to Finite state problem

The system state at time-slot t is denoted by a vector X(t) := (X<sub>1</sub>(t), ..., X<sub>N</sub>(t)). where X<sub>n</sub>(t) : Time elapsed since the latest delivery of client n's packet.

• The Action at time t is  $U(t) := (U_1(t), ..., U_N(t))$ , with  $\sum_{n=1}^N U_n(t) \le L$ 

$$U_n(t) = \begin{cases} 1 & \text{if client n is selected to transmit in slot t,} \\ 0 & \text{otherwise.} \end{cases}$$
(2)

The system state evolve as,

$$X_n(t+1) = \begin{cases} 0 & \text{if a packet of client n is delivered in t} \\ X_n(t) + 1 & \text{otherwise.} \end{cases}$$
(3)

The system forms a controlled Markov chain(MDP-1), with the transition probabilities given by,

$$P_{\mathbf{x},\mathbf{y}}^{MDP-1}(\mathbf{u}) := P[X(t+1) = \mathbf{y} | X(t) = \mathbf{x}, U(t) = \mathbf{u}]$$
  
=  $\prod_{n=1}^{N} P[X_n(t+1) = y_n | X_n(t) = x_n, U_n(t) = u_n]$  (4)

$$P[X_n(t+1) = y_n | X_n(t) = x_n, U_n(t) = u_n] := \begin{cases} p_n & \text{if } y_n = 0 \text{ and } u_n = 1, \\ 1 - p_n & \text{if } y_n = x_n + 1 \text{ and } u_n = 1, \\ 1 & \text{if } y_n = x_n + 1 \text{ and } u_n = 0, \\ 0 & \text{otherwise.} \end{cases}$$
(5)

The T-horizon optimal cost-to-go from initial state x is given by,

$$egin{aligned} V_{\mathcal{T}}(\mathbf{x}) &:= \min_{\pi: \Sigma_n U_n(t) \leq L} \mathrm{E}\{\sum_{t=0}^{T-1} \sum_{n=1}^N (\eta E_n U_n(t) + (X_n(t) + 1 - au_n)^+ 1\{X_n(t+1) = 0\}) | X(0) = \mathbf{x}\}, \end{aligned}$$

minimization is over the class of history dependent policies.

The Dynamic Programming (DP) recursion is,

$$V_{T}(\mathbf{x}) = \min_{\mathbf{u}:\Sigma_{n}u_{n} \leq L} E\{\eta \sum_{n=1}^{N} E_{n}u_{n} + \sum_{\mathbf{y}} P_{\mathbf{x},\mathbf{y}}^{\mathrm{MDP}-1}(\mathbf{u}) \\ [\sum_{n=1}^{N} (x_{n} + 1 - \tau_{n})^{+} 1\{y_{n} = 0\} + V_{T-1}(\mathbf{y})]\}$$
(2)

(日) (日) (日) (日) (日) (日) (日) (日)

MDP-1 involves infinite state space.

Lemma 1: For the MDP-I, we have,

 $\forall x_1, ..., x_N \ge 0, V_T(x_1, ..., \tau_i + x_i, ..., x_N) = x_i + V_T(x_1, ..., \tau_i, ..., x_N).$ Moreover, the optimal actions for the states  $(x_1, ..., \tau_i + x_i, ..., x_N)$  and  $(x_1, ..., \tau_i, ..., x_N)$  are the same. proof:

**Corollary 2:** For any system state x such that  $x_n \leq \tau_n, \forall n$ ,

$$\begin{aligned}
\mathcal{V}_{\mathcal{T}}(\mathbf{x}) &= \min_{\mathbf{u}: \Sigma_n u_n \leq L} \mathrm{E}\{\sum_n (\eta E_n u_n + 1\{x_n = \tau_n\}) \\
&+ \sum_{\mathbf{y}} \mathcal{P}_{\mathbf{x}, \mathbf{y}}^{\mathrm{MDP}-1} \mathcal{V}_{\mathcal{T}-1}(\mathbf{y} \wedge \tau)\}.
\end{aligned}$$
(3)

proof:

• Lemma 3:  $Y(t) := X(t) \land \tau$  is a Markov decision Process

with  $P[Y(t+1)|Y(t), \dots, Y(0), U(t), \dots, U(0)]$ = P[Y(t+1)|Y(t), U(t)]. By using the above results we can construct another MDP, denoted MDP-2, which is equivalent to the MDP-1.

Y(t): State U(t): control For  $Y_n(0) \in \{0, 1, ..., \tau_n\}$ , let  $Y_n(t)$  evolves as,

 $Y_n(t+1) = \begin{cases} 0 \text{ if a packet is delivered for client } n \text{ at } t, \\ (Y_n(t)+1) \wedge \tau_n \text{ otherwise.} \end{cases}$ 

The transition probabilities of MDP-2,  $P_{x,y}^{MDP-2}$ State space  $\mathbb{Y} := \prod_{n=1}^{N} \{0, 1, ... \tau_n\}$ 

$$P[Y_n(t+1) = y_n | Y_n(t) = x_n, U_n(t) = u_n] := \begin{cases} p_n & \text{if } y_n = 0 \text{ and } u_n = 1, \\ 1 - p_n & \text{if } y_n = (x_n + 1) \land \tau_n \& u_n = 1, \\ 1 & \text{if } y_n = (x_n + 1) \land \tau_n \& u_n = 0, \\ 0 & \text{otherwise.} \end{cases}$$

$$(4)$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

The optimal cost-to-go function for MDP-2 is,

$$V_{\mathcal{T}}(\mathbf{x}) := \min_{\pi: \Sigma_n U_n(t) \le L} \mathbb{E}\{\sum_{t=0}^{T-1} \sum_{n=1}^N (\eta E_n U_n(t), \forall \mathbf{x} \in \mathbb{Y} + 1\{Y_n(t) = \tau_n\} | Y(0) = \mathbf{x}\},$$
(5)

**Theorem 4**: MDP-2 is equivalent to the MDP-1 in that:

1. MDP-2 has the same transition probabilities as the accompanying process of MDP-1, i.e., the process  $X(t) \wedge \tau$ ;

2. Both MDPs satisfy the recursive relationship in (3); thus, their optimal cost-to-go functions are equal for each starting state x with  $x_n \le \tau_n$ ;

3. Any optimal control for MDP-1 in state x is also optimal for MDP-2 in state x  $\wedge\,\tau$ 

The Dynamic Programming recursion for the optimal cost in MDP-2 is

$$V_{T}(\mathbf{x}) = \min_{\mathbf{u}: \Sigma_{n} u_{n} \leq L} E\{\sum_{n} (\eta E_{n} u_{n} + 1\{x_{n} = \tau_{n}\}) + \sum_{\mathbf{y}} P_{\mathbf{x}, \mathbf{y}}^{\mathrm{MDP-2}} V_{T-1}(\mathbf{y})\}.$$
 (6)

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへで

#### Formulation of Restless Multi-armed bandit Problem

#### Notations:

- $\alpha = \frac{L}{N}$ , Maximum fraction of clients that can simultaneously transmit.
- $Y_n(t)$  associated with client n is denoted as project n.
- $U_n(t) = 1$ , if the project n is active in slot t.
- ▶  $U_n(t) = 0$ , if the project n is passive in slot t. The infinite-horizon problem is to solve, with  $Y(0) = \mathbf{x} \in \mathbb{Y}$ ,

$$\max_{\pi} \lim_{T \to +\infty} \inf_{\infty} \frac{1}{T} \mathbb{E} \left[ \sum_{t=0n}^{T-1} \sum_{n=1}^{N} -1 \{ Y_n(t) = \tau_n \} - \eta E_n U_n(t) \right]$$
(7)  
s.t. 
$$\sum_{n=1}^{N} (1 - U_n(t)) \ge (1 - \alpha) N, \forall t.$$
(8)

#### **Relaxations:**

We consider an associated relaxation of the problem which puts a constraint only on the *time average* number of active projects allowed:

$$\max_{\pi} \lim_{T \to +\infty} \inf_{\infty} \frac{1}{T} \mathbb{E} \left[ \sum_{t=0}^{T-1} \sum_{n=1}^{N} -1 \{ Y_n(t) = \tau_n \} - \eta E_n U_n(t) \right]$$
(9)  
s.t. 
$$\lim_{T \to +\infty} \inf_{\infty} \frac{1}{T} \mathbb{E} \left[ \sum_{t=0}^{T-1} \sum_{n=1}^{N} (1 - U_n(t)) \right] \ge (1 - \alpha) N.$$
(10)

Let us consider the Lagrangian associated with the problem (9)-(10), with  $Y(0) = \mathbf{x} \in \mathbb{Y},$ 

$$I(\pi, \omega) := \liminf_{T \to +\infty} \frac{1}{T} \mathbb{E}_{\pi} \left[ \sum_{t=0}^{T-1} \sum_{n=1}^{N} -1\{Y_n(t) = \tau_n\} - \eta E_n U_n(t) \right] \\ + \omega \liminf_{T \to +\infty} \frac{1}{T} \mathbb{E}_{\pi} \left[ \sum_{t=0}^{T-1} \sum_{n=1}^{N} (1 - U_n(t)) \right] - \omega (1 - \alpha) N,$$

 $\begin{aligned} \pi: \mbox{ History dependent scheduling policy.} \\ \omega \geq 0: \mbox{ Lagrangian multiplier} \end{aligned}$ 

The Lagrangian dual function is  $d(\omega) := \max_{\pi} l(\pi, \omega)$  :

$$d(\omega) \leq \max_{\pi} \lim_{T \to +\infty} \inf_{\infty} \frac{1}{T} \mathbb{E}[\sum_{t=0}^{T-1} \sum_{n=1}^{N} -1\{Y_n(t) = \tau_n\} -\eta E_n U_n(t) + \omega(1 - U_n(t)) | Y(0) = x] - \omega(1 - \alpha)N$$

$$\leq \max_{\pi} \limsup_{T \to +\infty} \frac{1}{T} \mathbb{E}[\sum_{t=0}^{T-1} \sum_{n=1}^{N} -1\{Y_n(t) = \tau_n\} -\eta E_n U_n(t) + \omega(1 - U_n(t)) | Y(0) = x] - \omega(1 - \alpha)N$$

$$\leq \max_{\pi} \sum_{n=1}^{N} \limsup_{T \to +\infty} \frac{1}{T} \mathbb{E}[\sum_{t=0}^{T-1} -1\{Y_n(t) = \tau_n\} -\eta E_n U_n(t) + \omega(1 - U_n(t)) | Y(0) = x] - \omega(1 - \alpha)N, \quad (11)$$

equation (11) is the unconstrained problem.

It can be viewed as a composition of N independent  $\omega$ -subsidy problems interpreted as follows: For each client n, besides the original reward  $-1{Y_n(t) = \tau_n} - \eta E_n U_n(t)$ , when  $U_n(t) = 0$ , it receives a subsidy  $\omega$  for being passive.

Thus, the  $\omega$ -subsidy problem associated with client n is defined as,

$$R_{n}(\omega) = \max_{\pi_{n}} \lim_{T \to +} \sup_{\infty} \frac{1}{T} E[\sum_{t=0}^{T-1} -1\{Y_{n}(t) = \tau_{n}\} -\eta E_{n} U_{n}!(t) + \omega(1 - U_{n}(t))|Y_{n}(0) = x_{n}],$$
(12)

(日) (日) (日) (日) (日) (日) (日) (日)

where  $\pi_n$  is a history dependent policy which decides the action  $U_n(t)$  for client n in each time-slot.

We first solve this  $\omega$ -subsidy problem, and then explore its properties to show that strong duality holds for the relaxed problem (9)-(10), and thereby determine the optimal relaxed policy.

- For  $\theta \in \{0, 1, ..., \tau_n\}$  and  $\rho \in [0, 1]$ , we define  $\sigma_n(\theta, \rho)$  to be a threshold policy for project *n*, as follows: The policy  $\sigma_n(\theta, \rho)$ at time t,  $Y_n(t) < \theta$  :Project is Passive i.e.,  $U_n(t) = 0$  $Y_n(t) > \theta$  :Project is Active i.e.,  $U_n(t) = 1$ If  $Y_n(t) = \theta$  : then, Project stays Passive with Probability  $\rho$ , and is activated with probability  $1 - \rho$ .
- For each project n, associate a function defined as,

$$W_n(\theta) := p_n(\theta+1)(1-p_n)^{\tau_n-(\theta+1)} - \eta E_n, \qquad (13)$$

The Whittle Index W<sub>n</sub>(i) of project n at state i is defined as the value of the subsidy that makes the passive and active actions equally attractive for the ω-subsidy problem associated with project n in state i. When ω = W<sub>n</sub>(i) The following holds the optimality,

$$-\eta E_n + \rho_n f(0) + (1 - \rho_n) f((i+1) \wedge \tau_n) = \omega + f((i+1) \wedge \tau_n)$$

- The n-th project is said to be indexable if:
  - B<sub>n</sub>(ω) be the set of states for which project n is passiveunder an optimal policy corresponding ω-subsidy problem.
  - Project n is indexable if, as ωincreases from −∞to +∞, the set B<sub>n</sub>(ω) increases monotonically from φ to the whole space.

**Lemma 5:** Consider the  $\omega$ -subsidy problem(12), for project n. Then,

• 
$$\sigma_n(0,0)$$
 is optimal iff the subsidy  $\omega \leq W_n(0)$ .

- ► For  $\theta \in \{1, ..., \tau_n 1\}$  is optimal iff the subsidy  $\omega$  satisfies  $W_n(\theta 1) \le \omega \le W_n(\theta)$ .
- $\sigma_n(\tau_n, 0)$  is optimal iff  $\omega = W_n(\tau 1)$ .
- $\sigma_n(\tau_n, 1)$  is optimal iff  $\omega \ge W_n(\tau 1)$ . In addition, for  $\theta \in \{1, ..., \tau_n - 1\}$ , the policies  $\{\sigma_n(\theta, \rho) : \rho \in [0, 1]\}$  are optimal when, 1.  $0 \le \theta \le \tau - 1$  and  $\omega = W_n(\theta)$ , 2.  $\theta = \tau$  and  $\omega = W_n(\tau - 1)$ . Furthermore, for any  $\theta \in \{1, ..., \tau\}$ , under the  $\sigma(\theta, 0)$  policy, the average reward earned is,

$$\frac{p_n\theta\omega-\eta E_n-(1-p_n)^{\tau_n-\theta}}{1+\theta p_n}.$$
 (14)

Consider the ω subsidy problem for project n,and denote by a<sub>n</sub>(θ, ρ) the average proportion of time that the active action is taken under the policy σ<sub>n</sub>(θ, ρ), i.e., a<sub>n</sub>(θ, ρ) := lim<sub>T→+∞</sub> <sup>1</sup>/<sub>T</sub> E<sub>σ<sub>n</sub>(θ,ρ)</sub>[∑<sup>T-1</sup><sub>t=0</sub> U<sub>n</sub>(t)]. Let a<sub>n,min</sub>(ω) := min<sub>θ,ρ</sub>{a<sub>n,min</sub>(θ, ρ) : σ<sub>n</sub>(θ, ρ)is optimal when the subsidy is ω}.

Theorem 7:For the relaxed problem (9)-(10) and its dual Fd(ω), the following results hold:

• The dual function  $d(\omega)$  satisfies,

$$d(\omega) = \sum_{n=0}^{N-1} R_n(\omega) - \omega(1-\alpha)N.$$
(13)

- Strong duality holds, i.e., the optimal average reward for the relaxed problem, denoted *R<sub>rel</sub>*, satisfies, *R<sub>rel</sub>* = min<sub>ω≥0</sub> d(ω)
- Define policy  $\sigma(\theta, \rho)$  as the one that applies  $\sigma_n(\theta_n, \rho_n)$  to each project n. Then, for each  $\alpha \in [0, 1]$ , there exist vectors  $\theta^*$  and  $\rho^*$  such that  $\sigma(\theta^*, \rho^*)$
- In addition, d(ω) is a convex and piecewise linear function of ω. Thus, the value of R<sub>rel</sub> can be easily solved.

### **Properties of** $d(\omega)$ :

- Each  $R_n(\omega)$  is a piecewise linear function.
- To prove convexity of R<sub>n</sub>(ω), note that the reward earned by any policy is a linear function of ω, and the supremum of linear functions is convex. Thus, d(ω) is also convex and piecewise linear.
- ▶ The value of  $R_{rel}$ , which is the minimum value of this known, convex, and piecewise linear function  $d(\omega)$ , can be easily obtained.

Whittle index policy: At the beginning of each time slot t, client n is scheduled if its whittle index  $W_n(Y_n(t))$  is positive, and moreover, is within the top  $\alpha N$  index values of all clients in that slot. Now not more than  $\alpha N$  clients are simultaneously scheduled.
