Authors: Ivan W. Selesnick and Ilker Bayram

$$\underset{\mathbf{x}\in\mathbb{R}^n}{\arg\min} \left\{ F(\mathbf{x}) = \frac{1}{2} ||\mathbf{y} - \mathbf{H}\mathbf{x}||_2^2 + \sum_{n=0}^{N-1} \lambda_n \phi_n(\mathbf{x}_n) \right\}$$

► To find "non convex" penalties ϕ_n which induce sparsity more strongly than ℓ_1 norm regularization such that overall objective function F(.) is convex.

Main Idea:

►

- Balance the +ve second derivative of fit error term against -ve second derivative of penalty terms.
- Select $\phi_n(x)$ to be parameterized functions $\phi_n(x; a_n)$, with parameter a_n .

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Candidates for φ_n:

Rewrite F(x) as

$$F(\mathbf{x}) = \left(\frac{1}{2}\mathbf{x}^{T}(\mathbf{H}^{T}\mathbf{H} - \mathbf{R})\mathbf{x} - \mathbf{y}^{T}\mathbf{H}\mathbf{x} + \frac{1}{2}\mathbf{y}^{T}\mathbf{y}\right) + \left(\frac{1}{2}\mathbf{x}^{T}\mathbf{R}\mathbf{x} + \sum_{n}\lambda_{n}\phi_{n}(\mathbf{x}_{n};n)\right)$$

where R is a +ve definite diagonal matrix

For ϕ_n being logarithmic penalty, the second term is convex if

$$0 < a_n < \frac{r_n}{\lambda_n} \tag{1}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

where $r_n = \mathbf{R}(n, n)$. So, we need to find **R** which satisfies (1).

How to find R

- Larger r_n synonymous with more non-convex φ_n and therefore more sparsity inducing.
- R found via optimization problem:

$$\underset{r_{1},r_{2}...r_{n}}{\operatorname{arg max}} \sum_{n=0}^{N-1} r_{n}$$
such that $r_{n} \geq \lambda_{min}(\mathbf{H}^{T}\mathbf{H})$ and $\mathbf{H}^{T}\mathbf{H} - \mathbf{R} \geq 0$

Near Optimal Sensor Placement for Linear Inverse Problems.

Authors: Juri Raniieri and Amina Chebira and Martin Vetterli

- Linear inverse problem: Find **x** from $\mathbf{y} = \Psi \mathbf{x}$.
- There are *N* measurements from different sensors, $\mathbf{y} \in \mathbb{R}^N$.
- Which are best L meaurements out of N total meaurements? (MSE wise)
- Combinatorial complexity.

Contributions:

- Fast greedy algorithm to pick best *L* measurements.
- Near optimality of greedy algorithm shown. (optimization in terms of MSE)
- Main Idea: Use Frame potential(FP) used as cost function.
- What is frame potential
 - For G ⊂ (1,2...N) and |G| = L, FP(Ψ_G) = ∑_{i,j∈G} | < ψ_i, ψ_j > |² where ψ_i and ψ_i are rows of submatrix Ψ_G.
 - ▶ FP is a measure of orthogonality of rows. (Lower FP \Rightarrow tighter frame).

Why frame potential?

- MSE based cost functions suffer from local minimas.
- ▶ It is shown that $FP(\Psi_G) \rightarrow FP_{UNTF}$ implies $MSE(\Psi_G) \rightarrow MSE_{UNTF}$.
- FP is easy to compute.
- FP is shown to be submodular in G and greedy algorithms are known to be optimal in optimization of submodular functions.

FrameSense - a greedy algorithm to pick best L out of N measurements

- ► In each iteration, remove the row that maximizes $FP(\Psi_S) = FP(\Psi) FP(\Psi_{N \setminus S})$.
- ► S = set of unwanted rows/measurements and N = (1, 2, ..., N)

Distributed Sparse Recursive Least-Squares Over Networks.

Authors: Zhaoting Liu, Ying Liu and Chunguang Li

- Distributed online learning of sparse vector
- Measurement model at time instant i.

$$d_{n,i} = \mathbf{u}_{n,i}\mathbf{w} + \eta_{n,i}$$

- $\mathbf{w} \in \mathbb{R}^M$ is sparse, $d_{n,i}$ is measurement taken at node $n \eta_{n,i} \sim \mathcal{N}(\mathbf{0}, \sigma_n^2)$.
- Contributions: Distributed RLS algorithm for learning w.
- Main ideas:
 - Each node n minimizes local cost function

$$\psi_{n,i} = \arg \max_{\mathbf{w}} \sum_{l \in N_n} \sum_{j=1}^{i} \mu^{i-j} \log p(d_{l,i}/\mathbf{w}) - \gamma J(\mathbf{w})$$
(2)

- J(w) is sparsity inducing penalty term.
- Local cost function (2) simplifies to:

$$\psi_{n,i} = \arg\min_{\mathbf{w}} \sum_{l \in N_n} \frac{(\mathbf{d}_{l,i} - \mathbf{U}_{l,i}\mathbf{w})^T \Lambda_i(\mathbf{d}_{l,i} - \mathbf{U}_{l,i}\mathbf{w})}{2\sigma_l^2} + \gamma J(\mathbf{w})$$

where $\mathbf{d}_{l,i} = (d_{n,1}, \dots, d_{n,i})$ and $\mathbf{U}_{l,i} = \operatorname{col}(\mathbf{u}_{n,1}, \dots, \mathbf{u}_{n,i})$ and $\Lambda_i = \operatorname{diag}(\mu_{i-1}, \mu_{i-2} \dots 1)$

As *i* increases, dimensions of d_{1,i}, U_{1,i}, Λ_i increase. So RLS type algorithm is needed!

Main ideas (contd):

Combined measurement model for *i* time instances at node *n*:

$$\mathbf{d}_{n,i} = \mathbf{U}_{n,i}\mathbf{w} + \boldsymbol{\xi}_{n,i} \tag{3}$$

Trick: Decompose noise vector ξ_{n,i} into two parts:

$$\boldsymbol{\xi}_{n,i} = \alpha_n \mathbf{U}_{n,i} \boldsymbol{\mu}_{n,i} + \Lambda_i^{\frac{1}{2}} \boldsymbol{\nu}_{n,i}$$
(4)

where $\nu_{n,i} \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I} - \alpha_n^2 \Lambda_i^{\frac{1}{2}} \mathbf{U}_{n,i} \mathbf{U}_{n,i}^T \Lambda_i^{\frac{1}{2}})$ and $\mu_{n,i} = \mathcal{N}(0, \mathbf{I})$.

Using (3) and (4), we can write

$$\mathbf{z}_{n,i} = \mathbf{w} + \alpha_n \boldsymbol{\mu}_{n,i} \tag{5}$$

$$\mathbf{d}_{n,i} = \mathbf{U}_{n,i} \mathbf{z}_{n,i} + \Lambda_i^{\frac{1}{2}} \boldsymbol{\nu}_{n,i}$$
(6)

Using (5) and (6), we can now formulate EM algorithm !

E-step:

$$Q(\mathbf{w}, \hat{\mathbf{w}}_{n,i-1}) = E_z[\log p(\mathbf{d}_{l,i}, \mathbf{z}_{l,i}/\mathbf{w})|\mathbf{d}_{l,i}, \hat{\mathbf{w}}_{n,i-1}].$$

modified M-step:

$$\arg\max_{\mathbf{w}} \sum_{l \in N_n} Q_l(\mathbf{w}, \hat{\mathbf{w}}_{n,i-1}) - \gamma J(\mathbf{w}).$$

Decentralized Dynamic Optimization Through the Alternating Direction Method of Multipliers

Authors: Qing Ling and Alejandro Ribeiro

Dynamic optimization problem with separable cost function @ time instant k:

$$\min_{\mathbf{x}} \sum_{i=1}^{L} f_i^k(\mathbf{x})$$

where $\mathbf{x} \in \mathbb{R}^{p}$.

 Can be formulated as a decentralized consensus optimization problem, given by

$$\min_{\mathbf{x}_1, \mathbf{x}_2...\mathbf{x}_L} \sum_{i=1}^n f_i^k(\mathbf{x}_i) \qquad \text{ such that } \mathbf{x}_i = \mathbf{x}_j \forall i, j \in (1, 2...L)$$

Need a decentralized algorithm whose iterations consider same time scale as the evolution of the functions f^k_i(.).

Main Results:

- Decentralized ADMM suggested for above problem (run single ADMM iteration in each time instant).
- In steady state, bounds on tracking error provided.
- Steady state tracking error and decay of primal gap before reaching steady state depends on:

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- 1. Condition number of underlying graph
- 2. Condition number of objective function of primal problem
- 3. $\max_{k} ||\mathbf{x}_{k}^{*} \mathbf{x}_{k-1}^{*}||_{2}$

4.
$$\max_{k} ||\nabla f_k(\mathbf{x}_k^*) - \nabla f_{k-1}(\mathbf{x}_{k-1}^*)||_2$$
